

# AI CONTENT WRITING WORKFLOW

**Draft → Critique → Revise**

## 1. Purpose

The purpose of this workflow is to create clear and professional portfolio content from raw project information. Instead of using one prompt to directly generate the final content, I divided the process into three separate steps: drafting, critiquing, and revising.

The workflow is designed for software engineering projects and UI/UX case studies. It helps reduce repetitive writing and editing work while keeping the final content based on the information I provide.

## 2. Workflow Diagram

### **Handoffs**

- **Step 1 → Step 2:** The first draft is passed to the critique step.
- **Step 2 → Step 3:** The critique and original draft are used to produce the revised version.
- **Step 3:** Produces the final portfolio-ready content.

## 3. Tool Used

## **Claude Project**

I used a Claude Project because it allows persistent instructions to be defined once and then reused across multiple project inputs. No coding or automation platform was required.

## **4. Project Configuration**

### **Project Name**

### **Portfolio Content Writing Workflow**

### **Project Instructions**

You are my portfolio content writing assistant.

Your job is to help me turn rough project information into clear, evidence-based portfolio content.

My portfolio includes software engineering projects and UI/UX case studies.

Follow this workflow:

#### **STEP 1 — DRAFT**

Create a first draft from the user's input.

Do not invent facts, numbers, results, technologies, or achievements.

Use only information provided by the user.

#### **STEP 2 — CRITIQUE**

Review the draft for:

- clarity
- accuracy
- structure
- unnecessary repetition
- unsupported claims
- weak or vague statements
- whether the content clearly communicates the user's contribution

#### **STEP 3 — REVISE**

Create a final version using the critique.

Keep the user's actual experience and facts.

Do not add information that was not provided.

For every input, clearly label:

STEP 1 — DRAFT

STEP 2 — CRITIQUE

STEP 3 — REVISED VERSION

The final version should be concise, professional, specific, and suitable for a student software engineering/UI/UX portfolio.

## **5. Step 1 : Draft Prompt**

Create a first draft from the project information below.

Focus on:

- what the project is
- the problem or purpose
- what I personally worked on
- technologies/tools used
- important features
- outcome, if provided

Do not invent missing information.

PROJECT INFORMATION:

[PASTE PROJECT INFORMATION HERE]

### **Handoff**

The generated draft becomes the input for Step 2.

## **6. Step 2 : Critique Prompt**

Critique the draft above.

Check:

1. Is it clear what the project does?
2. Is my personal contribution clear?
3. Are the technologies and claims supported by the input?
4. Is anything vague, repetitive, or unnecessary?
5. Is there evidence for the stated outcome?
6. What should be changed before publishing?

Give specific recommendations.

Do not rewrite the entire piece yet.

### **Handoff**

The critique is passed to Step 3 along with the original draft.

## **7. Step 3 :Revise Prompt**

Revise the draft using the critique.

Requirements:

- Keep all factual information accurate.
- Do not invent details.
- Clearly communicate my contribution.
- Remove unnecessary repetition.
- Make the writing concise and professional.
- Keep it suitable for a software engineering/UI/UX portfolio.

Return only the final revised version.

## **8. Five Real Runs**

The workflow was tested on five real portfolio projects rather than only on sample inputs.

### **Run 1 : Internship CRUD API**

**Input:**

A JavaScript REST API for managing tasks, built using Express.js and SQLite. The project included CRUD operations, persistent storage, Swagger/OpenAPI documentation, and Thunder Client testing.

**Workflow output:**

The workflow produced a structured project description, identified repetition in the first draft, and revised it to emphasize my contribution, technical stack, CRUD functionality, SQLite persistence, API documentation, and testing.

**Result:**

A concise portfolio-ready project description was produced.

### **Run 2 : CommandDesigner**

**Input:**

A CASE tool developed as a Software Design and Architecture course project using client-server architecture, MVC, and DAO patterns.

**Workflow output:**

The workflow converted the project information into a structured description and used the critique stage to identify areas where the technical architecture and personal contribution needed clearer explanation.

**Result:**

A more organized project description suitable for a software engineering portfolio was produced.

### **Run 3 :InventoryIQ**

**Input:**

An inventory management application developed as a software engineering project.

**Workflow output:**

The workflow generated a first draft, reviewed it for vague or unsupported claims, and produced a revised version based only on the information provided.

**Result:**

A structured project description was produced while avoiding invented features or results.

### **Run 4 :E-commerce App**

**Input:**

A web-based e-commerce application developed as a software engineering project to provide an online shopping experience.

**Workflow output:**

The workflow created a draft describing the project's purpose and functionality, critiqued areas where more specific information would be useful, and revised the content without inventing missing technical details.

**Result:**

A concise portfolio description was produced with incomplete information clearly handled rather than fabricated.

### **Run 5:Steady UX Case Study**

**Input:**

Steady is a UX/UI project for a dental and medical-anxiety companion app. The project includes user research/personas, wireframes, high-fidelity designs, and planned features such as appointment preparation, communication tools, grounding exercises, and progress tracking. The project is still in progress.

**Workflow output:**

The workflow identified that the project was still incomplete and avoided presenting planned features or results as completed work.

**Result:**

A portfolio description was produced that clearly communicates the concept, UX/UI work, tools, planned features, and current work-in-progress status.

## **9. Time Accounting**

I did not use a stopwatch during the five runs, so the following figures are **estimates rather than measured times**.

- **Setup time:** approximately 30–45 minutes
- **Estimated manual average per input:** approximately 20–25 minutes
- **Estimated workflow average per input:** approximately 8–12 minutes
- **Estimated time saved:** approximately 10–15 minutes per input

The workflow has an initial setup cost because the project instructions and prompts have to be created. However, after setup, the same workflow can be reused for new projects without rebuilding the process.

The time saving mainly comes from separating drafting, critique, and revision into a repeatable process instead of manually performing each step from scratch.

## **10. Failure Points**

The workflow worked well for structured project information, but there are several limitations:

- If the input is incomplete, the output may also be incomplete.
- AI may make writing sound more impressive than the evidence supports, so unsupported claims need to be checked.
- AI may misunderstand my personal contribution if I do not clearly describe what I worked on.
- The critique step can identify missing information but cannot provide information that was never supplied.
- AI may remove useful technical details when trying to make the writing concise.
- Planned features can accidentally be presented as completed features if the project status is not clearly stated.
- The workflow does not independently verify whether technical claims or project results are true.

## **11. Human Review Required**

Human review is still necessary before publishing the final content.

I need to check:

- **Factual accuracy :** Are all technologies and features correct?
- **Personal contribution :** Does the content accurately describe what I actually did?
- **Project status :** Are completed and planned features clearly separated?
- **Results and claims :** Are there any unsupported achievements or numbers?
- **Technical accuracy :** Are the technical descriptions correct?
- **Final wording :** Does the content sound like my own work and communication style?

The AI helps with structure and refinement, but I remain responsible for verifying the final content.

## **12. Conclusion**

This workflow changed the process from using a single prompt into a repeatable three-step system: **Draft** → **Critique** → **Revise**. I tested it on five real portfolio projects covering both software engineering and UI/UX work.

The workflow is reusable because the same project instructions and prompts can be applied to a brand-new project input. Its main benefit is reducing repetitive writing and revision work while maintaining a human review step for accuracy and authenticity.

The biggest limitation is that the quality of the final output depends on the quality and completeness of the information provided. **AI can improve and structure my content, but I still need to provide the facts and verify the final result.**
