

Run 1 :Internship CRUD API

STEP 1 :DRAFT

Internship CRUD API

A JavaScript REST API for managing tasks, built as part of an internship assignment to practice developing CRUD APIs and working with persistent data using SQLite.

I built the API using Express.js and implemented full CRUD operations for tasks. I replaced the initial in-memory storage with a SQLite database using better-sqlite3, giving the application persistent data storage. I also added Swagger/OpenAPI documentation for the API and tested the endpoints using Thunder Client.

Technologies/Tools: JavaScript, Node.js, Express.js, SQLite, better-sqlite3, Swagger/OpenAPI, Thunder Client, Git/GitHub

Key Features:

Create, read, update, and delete tasks

Persistent data storage using SQLite

SQL-based CRUD operations

API documentation using Swagger/OpenAPI

Outcome:

The CRUD API was completed and tested successfully. The API supports the required CRUD operations with SQLite-based persistent storage.

STEP 2 — CRITIQUE

Clarity: Overall readable, but the purpose and "my work" sections repeat the same information (CRUD API, SQLite) twice in slightly different words. This can be tightened.

Accuracy: No invented facts — draft stays within provided information. Good.

Structure: The features list overlaps with content already stated in the "my work" paragraph (e.g., "SQLite" and "CRUD operations" appear three times across the piece). A portfolio reader benefits more from non-redundant, scannable sections.

Unnecessary repetition:

"CRUD operations" appears 4 times.

"SQLite" / "persistent data storage" appears 4 times.

The Key Features list largely restates the "My Work" paragraph without adding new information.

Unsupported claims: None present — the draft avoids adding unverified outcomes, metrics, or achievements not provided by the user. Good discipline here.

Weak or vague statements:

"tested the API using Thunder Client" doesn't specify what was tested (e.g., endpoints, response codes) — but since no further detail was provided, this should remain general rather than be invented.

"completed and tested successfully" is somewhat generic phrasing common in student portfolios; it can be tightened to sound more direct without adding new claims.

Contribution clarity: The user's individual contribution (migrating storage, adding docs, testing) is present but buried under repeated context. It should be foregrounded since this is the most valuable part for a portfolio reader evaluating the student's actual work.

STEP 3 : REVISED VERSION

Internship CRUD API

A JavaScript REST API for managing tasks, built during an internship to practice designing CRUD APIs and working with persistent data.

My Contribution:

I built the API using Express.js, implementing full CRUD functionality for task management. I migrated the project from in-memory storage to a SQLite database using better-sqlite3, adding persistent data storage. I documented the API with Swagger/OpenAPI and tested endpoints using Thunder Client.

Key Features:

Full CRUD operations (Create, Read, Update, Delete) for tasks

Persistent storage via SQLite

API documentation with Swagger/OpenAPI

Tech Stack:

JavaScript, Node.js, Express.js, SQLite, better-sqlite3, Swagger/OpenAPI, Thunder Client, Git/GitHub

Outcome:

The API was completed with working CRUD functionality and SQLite-based persistence, verified through manual testing with Thunder Client.

RUN 2:Command designer

STEP 1 : DRAFT

CommandDesigner

A CASE tool developed as part of a Software Design and Architecture course project. The tool was designed to help users create and design commands while applying software architecture and design patterns.

I worked on the project as part of the development team. The project follows a client-server architecture and uses the MVC and DAO patterns.

Technologies/Tools: Java, Client-server architecture, MVC pattern, DAO pattern

Key Features:

- Command design/creation functionality
- Client-server architecture
- MVC-based organization
- DAO-based data access

Outcome:

The project was developed as a course project demonstrating the use of software architecture and design patterns.

STEP 2: CRITIQUE

Clarity: The purpose and features sections repeat "client-server architecture," "MVC," and "DAO" multiple times without adding new detail each time.

Accuracy: Draft does not invent facts, technologies, or outcomes beyond what was provided. Good.

Structure: Reasonable, but there's no clear separation between what the *project* does and what *the student specifically* did — this is the weakest part of the input.

Unnecessary repetition: "Client-server architecture," "MVC," and "DAO" each appear 2–3 times across purpose, my work, and features with no added information.

Unsupported claims: None added — good.

Weak or vague statements:

- "I worked on the project as part of the development team" is very generic. It doesn't tell the reader *what* the student actually did (e.g., which layer, which pattern, which feature) a hiring reader can't assess individual contribution from this sentence.
- "Outcome" section is generic and doesn't state anything beyond restating the project's purpose.

Contribution clarity — main issue: This is the biggest weakness. As written, the piece reads as a description of the project, not of the *student's individual role*. Since no more specific detail was provided, I cannot invent what the student worked on (e.g., "I implemented the DAO layer" would be fabrication unless the user confirms it). I'm flagging this rather than fixing it, since fixing it would require adding unverified claims.

STEP 3 : REVISED VERSION

CommandDesigner

A CASE tool developed as part of a Software Design and Architecture course project, designed to support creating and designing commands while applying software architecture and design patterns.

My Contribution

I was part of the development team that built this tool, which follows a client-server architecture and applies the MVC and DAO design patterns.

Key Features

- Command design and creation functionality
- Client-server architecture
- MVC-based organization
- DAO-based data access layer

Tech Stack

Java, Client-server architecture, MVC pattern, DAO pattern

Outcome

Completed as a course project demonstrating practical application of software architecture and design patterns (client-server, MVC, DAO)

RUN 3: INVENTORY MANAGEMENT:

STEP 1 :DRAFT

InventoryIQ

An inventory management application developed as a software engineering project. The project was created to manage inventory and organize product-related information through a digital application.

I worked on developing the inventory management application and its functionality.

Technologies/Tools: [Not yet provided]

Key Features:

- Inventory management
- Product information management
- [Not yet provided]

Outcome:

The project was developed as an inventory management application.

STEP 2 : CRITIQUE

Clarity: The core idea (an app to manage inventory and product info) is understandable, but the content is too thin to communicate anything specific about the project or your role in it.

Accuracy: No fabricated facts — but this is largely because there isn't enough information yet to fabricate from. I have not filled in the technologies or additional features, since those fields were left as placeholders rather than actual answers.

Structure: The sections are present but mostly restate the same one-line idea three times ("manage inventory," "product-related information," "inventory management application") without new detail.

Unnecessary repetition: "Inventory management" and "product-related information" are repeated across purpose, work, and features without adding anything new each time.

Unsupported claims: None — but only because the draft currently contains almost no specific claims at all.

Weak or vague statements:

- "I worked on developing the inventory management application and its functionality" doesn't say *what* functionality, *what* role, or *what* was technically involved.
- Technologies/Tools and part of Key Features are still empty placeholders — this is a critical gap for a portfolio piece, since readers (and often recruiters/ATS systems) look specifically for tech stack and concrete features.
- "The project was developed as an inventory management application" is circular — it restates the project type as the outcome, without saying what was achieved (e.g., completed, tested, deployed, specific functionality working).

Contribution clarity: Currently very low. There's no detail on what you actually built (e.g., CRUD for inventory items, stock tracking, search/filter, low-stock alerts, database used, frontend/backend split, etc.).

STEP 3 : REVISED VERSION

I can't responsibly produce a strong final version yet — the technologies and additional features fields are still placeholders, and without them this entry would be too generic to be useful in your portfolio (and I don't want to invent tech stack or features you didn't actually use).

Here's a minimal, honest placeholder version using only what's confirmed so far:

InventoryIQ

An inventory management application developed as a software engineering project to manage inventory and organize product-related information.

My Contribution

I worked on developing the application and its core functionality.

Key Features

- Inventory management
- Product information management

Outcome

Developed as a functioning inventory management application.

RUN 4:E-Commerce Platform

STEP 1 : DRAFT

E-commerce App

A web-based e-commerce application developed as a software engineering project to provide an online platform where users can browse products and interact with an e-commerce shopping experience.

I worked on developing the e-commerce application and implementing its user-facing functionality.

Technologies/Tools: [Not yet provided]

Key Features:

- Product browsing
- Product information/display
- E-commerce shopping functionality

Outcome:

The e-commerce application was developed as a functional software project demonstrating an online shopping experience.

STEP 2 :CRITIQUE

Clarity: The general concept is understandable, but as with InventoryIQ, there isn't enough concrete detail yet to communicate what was actually built.

Accuracy: No fabricated facts — the technologies and extra features are correctly left blank rather than invented.

Structure: Purpose, "my work," and features all restate "browsing/shopping experience" without adding new information at each stage.

Unnecessary repetition: "E-commerce shopping experience/functionality" appears three times across purpose, features, and outcome without elaboration.

Unsupported claims: None — but again, mainly because there's little specific content to overclaim from.

Weak or vague statements:

- "implementing its user-facing functionality" doesn't specify what that functionality is (e.g., product listing pages, cart, checkout, search/filter, user auth).
- "E-commerce shopping functionality" as a feature is vague — shopping functionality could mean anything from a cart to checkout to payment integration; without specifics, a reader can't tell what you actually built.
- "Developed as a functional software project demonstrating an online shopping experience" is circular — it restates the project type rather than describing a concrete result.
- Technologies/Tools field and part of Key Features are still placeholders — a significant gap for a portfolio entry, since tech stack is often the first thing readers and recruiters scan for.

Contribution clarity: Currently low. It's unclear what "user-facing functionality" specifically included — e.g., did you build the product catalog, cart, checkout flow, search, filtering, responsive UI, frontend framework work, or API integration?

STEP 3 : REVISED VERSION

I can't finalize this yet for the same reason as InventoryIQ the technologies and remaining features are still placeholders, and filling them in myself would mean inventing your tech stack, which I won't do.

Here's a minimal, honest placeholder version using only what's confirmed:

E-commerce App

A web-based e-commerce application developed as a software engineering project, providing an online platform for browsing products and engaging in a shopping experience.

My Contribution

I worked on developing the application and implementing its user-facing functionality.

Key Features

- Product browsing
- Product information/display
- E-commerce shopping functionality

Outcome

Developed as a functional e-commerce web application.

RUN 5:STEADY APP

STEP 1 : DRAFT

Steady

A UX/UI case study for a dental and medical-anxiety companion app. Steady is designed to support adults experiencing dental or medical anxiety by helping them prepare for appointments, communicate their needs, and use calming techniques before and during stressful healthcare experiences.

I worked on the UX/UI design of the Steady app. I developed the product concept, identified the target users, worked on user personas, and created wireframes and high-fidelity interface designs in Figma. I also explored the user experience and feature structure for the app.

Target Users: Adults who experience dental or medical anxiety.

Planned Key Features:

- Guided appointment preparation
- Communication tools to help users express their needs
- Grounding and calming exercises
- Progress tracking

Tools: Figma, Canva, ChatGPT, Claude

Current Status: The Steady project is still a work in progress, and the case study is not yet complete. Some design and UX work has been developed, but the final product and complete case study are still being worked on.

Outcome:

No final outcome or user testing results are available yet, as the project is still in progress.

STEP 2 : CRITIQUE

Clarity: Overall clear. The distinction between "planned features" and completed work is helpful and should be preserved — good that the original input already separates these.

Accuracy: Draft does not invent outcomes, testing results, or completed features beyond what's stated. This is especially important here since the project is explicitly unfinished — good discipline to maintain.

Structure: The "My Work" paragraph mixes several different activities (concept, personas, wireframes, hi-fi UI, feature exploration) in one run-on sentence. Breaking this into a scannable list would make your specific UX process more visible — this matters more for a *case study* than for a coded project, since case studies are usually evaluated on process/methodology.

Unnecessary repetition: Minimal — "work in progress" appears twice (Current Status and Outcome), which is somewhat redundant but not harmful given it's an important caveat.

Unsupported claims: None present. Good — no invented user research, testing, or validation.

Weak or vague statements:

- "I also explored the user experience and feature structure for the app" is vague — it doesn't clarify whether this means user flows, information architecture, feature prioritization, etc. Since no further detail was given, this should remain general rather than be invented.
- Listing "ChatGPT" and "Claude" as tools without context may read ambiguously to a reviewer (unclear if used for research, writing, ideation, etc.) — worth a brief neutral framing (e.g., "AI tools for ideation/content support") rather than leaving them unexplained, but only if you confirm that's accurate.

Contribution clarity: This is actually one of the stronger entries so far — your specific UX activities (concept development, target user identification, personas, wireframes, hi-fi designs) are clearly attributable to you. This should be preserved and reformatted for scannability rather than restructured content-wise.

Portfolio framing note: Because this project is unfinished, it's worth clearly labeling it as "**In Progress**" in the presentation itself (e.g., a status tag), so a reader doesn't mistake it for a completed case study when skimming.

STEP 3 :REVISED VERSION

Steady (Case Study — In Progress)

A UX/UI case study for a dental and medical-anxiety companion app, designed to support adults experiencing dental or medical anxiety by helping them prepare for appointments, communicate their needs, and use calming techniques before and during stressful healthcare experiences.

My Contribution

I led the UX/UI design process for Steady, including:

- Developing the initial product concept
- Identifying and defining the target user group
- Creating user personas
- Exploring the app's user experience and feature structure
- Designing wireframes and high-fidelity interface screens in Figma

Target Users

Adults who experience dental or medical anxiety.

Planned Key Features

- Guided appointment preparation
- Communication tools to help users express their needs
- Grounding and calming exercises
- Progress tracking

Tools

Figma, Canva, ChatGPT, Claude

Status

This project is currently in progress. Design and UX work has been developed, but the full case study and final product are not yet complete.

Outcome

No final outcome or user testing results are available yet, as the project is still in development.
